## I. Supplementary notes

*StatsPro* integrates 12 common statistical methods and 6 P-value combination strategies, and then provides three evaluation criteria to assess the performance of each method or strategy (described in Table S1). This tool is expected to help scientists detect the differentially expressed proteins and realize the ability of different statistical methods in a systematic view. Here we present the detailed introduction and operation of *StatsPro*, by which users can follow to analyze their own data freely and conveniently.

Users can visit this site: <https://www.omicsolution.com/wukong/StatsPro>. Then the website homepage can be shown like this:

StatsPro is developed by [R shiny \(Version 1.3.2\)](#), and is free and open to all users with no login requirement. It can be readily accessed by all popular web browsers including Google Chrome, Mozilla Firefox, Safari and Internet Explorer 10 (or later), and so on. We would highly appreciate that if you could send your feedback about any bug or feature request to Shisheng Wang at [wsslearning@omicsolution.com](mailto:wsslearning@omicsolution.com).

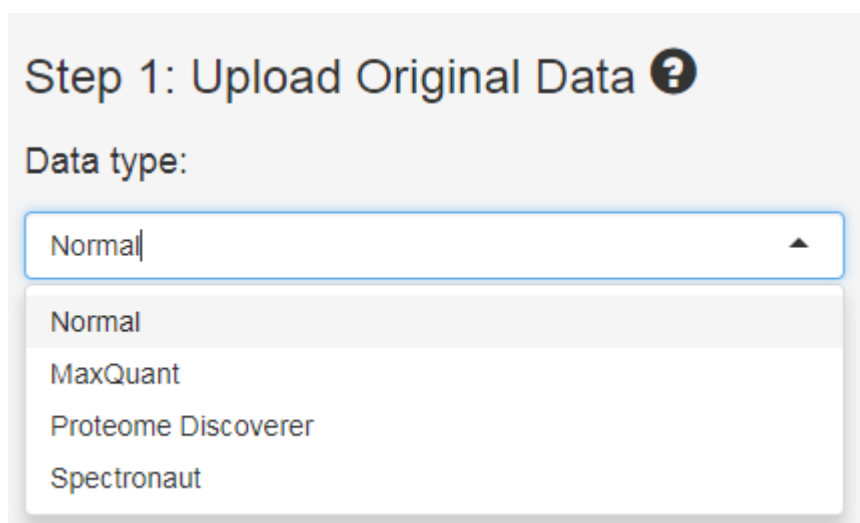

~~ Enjoy yourself in StatsPro ~~

## 1. Data Preparation

The uploaded data file formats could be .csv, .txt, .xlsx or .xls. Before analysis, users should prepare the proteomics expression data and sample information. The proteomics expression data required here could be readily generated based on results of several popular tools such as MaxQuant<sup>1</sup>, Proteome Discoverer (Thermo Fisher Scientific), Spectronaut<sup>2</sup>. Users then can upload the data and type in right sample information into *StatsPro* with right formats respectively and start subsequent analysis.

### 1.1 Expression data

There are currently four types of proteomics expression data supported in *StatsPro* (i.e., 'Normal', 'MaxQuant', 'Proteome Discoverer', 'Spectronaut'). The detailed description about this parameter is shown below:

The screenshot shows a web interface titled "Step 1: Upload Original Data" with a help icon. Below the title is a label "Data type:" followed by a dropdown menu. The dropdown menu is open, showing four options: "Normal", "MaxQuant", "Proteome Discoverer", and "Spectronaut". The "Normal" option is currently selected and highlighted.

#### 1.1.1 Normal type

"Normal" here means users can prepare their proteomics expression data as this type from any software (not just MaxQuant, Proteome Discoverer and Spectronaut) and upload into this tool. In the situation, protein ids/names and peptides number are sequentially provided in the first two columns of input file. The protein ids/names in the first column could be UniProt ids or protein names. The peptides number in the second column could be the total counts of peptides associated with the protein. From the third column, proteins expression intensity or signal abundance in every sample should be listed. The data structure is shown as below:

Protein ids/names

		Sample names					
Accession	PeptidesNum	U500_R1	U500_R2	U500_R3	U12500_R1	U12500_R2	U12500_R3

### 1.1.3 Proteomics data from Proteome Discoverer

If users choose Proteome Discoverer to process their raw MS data, they could export proteomics data as below and then upload this file into *StatsPro* directly:

a. Select the “Proteins” table and click “File—Export—To Microsoft Excel...”, as below:

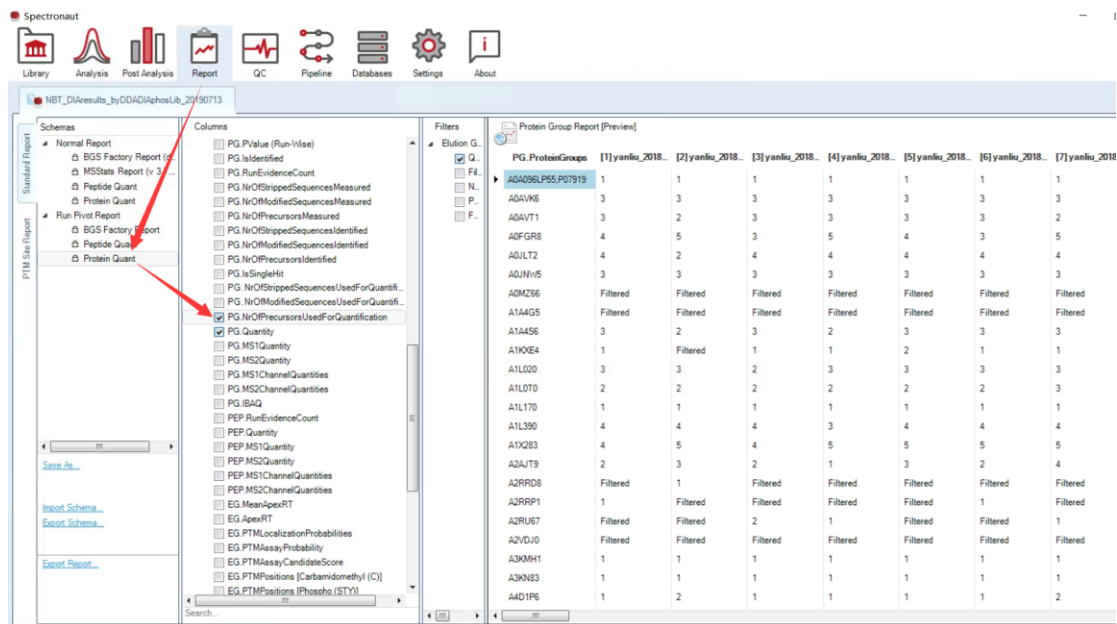

b. Export data to an excel file (.xlsx format) and then upload this file to *StatsPro* directly:

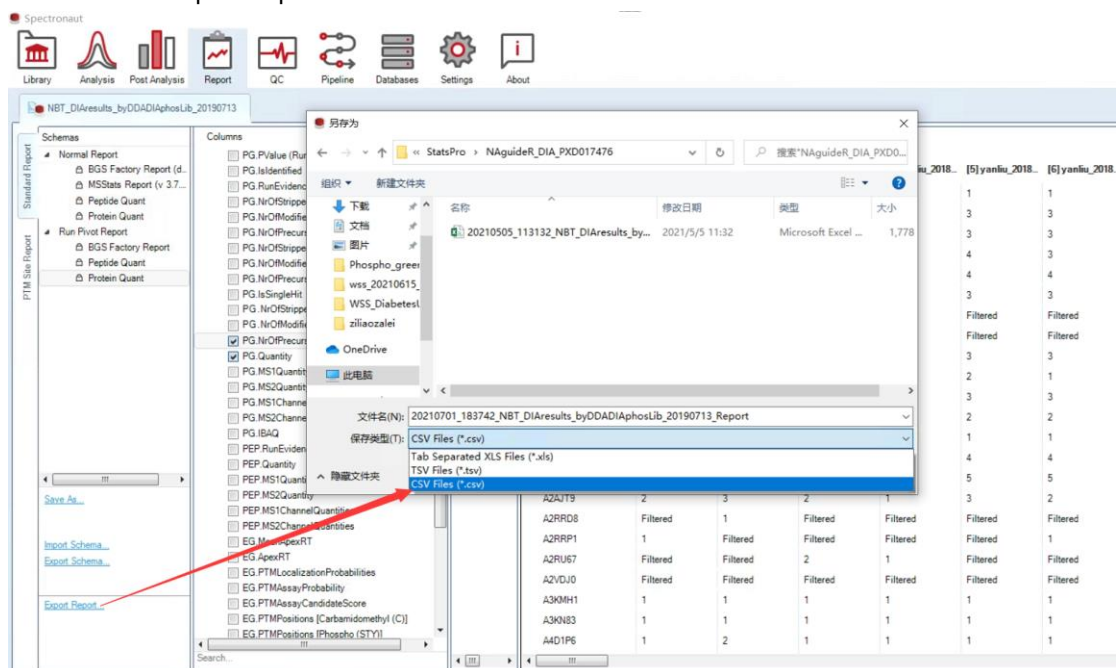

### 1.1.4 Proteomics data from Spectronaut

If users choose Spectronaut to process their raw MS data, they could export proteomics data as below and then upload this file into *StatsPro* directly:

a. Select the “Report” button and click “Protein Quant” in the “Run Pivot Report”. Besides the default options, users should also select the “PG.NrOfPrecursorsUsedForQuantification”, as below:

b. Then click “Export Report...” and save the data in a .csv file:

## 1.2 Samples information data

Sample information here means that users should provide group number, replicate number, and group names, then type them in *StatsPro* (see below). This tool will use these information to calculate corresponding results and enable, for example, filtration strategy for different group respectively in a later step:

## Samples information:

### 2.1 Group and replicate number:

2;3-3

### 2.2 Group names:

U5000;U12500

**2.1 Group and replicate number:** Type in the group number and replicate number here. Please note, the group number and replicate number are linked with ";", and the replicate number of each group is linked with "-". For example, if you have two groups, each group has three replicates, then you should type in "2;3-3" here. Similarly, if you have 3 groups with 5 replicates in every groups, you should type in "3;5-5-5".

**2.2 Group names:** Type in the group names of your samples. Please note, the group names are linked with ";". For example, there are two groups in the spiked data (UPS1+Yeast), you can type in "U5000;U12500".

## 1.3 Download example datasets

If users want to download the example datasets to their own computer and check the data format locally, they can download them from here:

*StatsPro*

Step 1: Upload Original Data

Data type:  
Normal

Upload experimental data Load example data

Download example expression data

Samples information:  
2.1 Group and replicate number:

First, select "Load example data" and the example data will be shown on the right panel interactively. Users can visually observe what the data looks like.

Second, users can download the example data (proteomics expression data) by clicking the "Download example expression data" button. The data are saved as corresponding format and users can open them in other software, such as Excel.

Third, users can check the example sample information and understand these parameters better.

## 2. Import Data

This is the first step, in which users should upload data here or load the example data with the above data formats. By default, we use the example data to show result of every step.

**2.1 Uploading data.** When users prepare their data (expression and sample information data set), they can upload these data from here:

The screenshot displays the 'StatsPro' 'Import Data' interface. It features a top navigation bar with links to 'Welcome', 'Import Data', 'Data Preprocessing', 'Statistical Methods', and 'Results and Assessments'. The main area is split into two panels. The left panel, labeled '1. Parameter panel', contains 'Step 1: Upload Original Data' with a 'Data type' dropdown set to 'Normal', radio buttons for 'Upload experimental data' (selected) and 'Load example data', and sections for '1. Expression data' (with a 'Browse...' button and checkboxes for 'First row as column names?' and 'First column as row names?') and '2. Samples information' (with input fields for '2.1 Group and replicate number' and '2.2 Group names'). The right panel, labeled '2. Results panel', shows '1. Expression data' with a table containing one entry: 'StatsPro detects that you did not upload your data. Please upload the expression data, or load the example data to check first.' The table has columns 'Show' (10 entries) and 'Description'. Navigation buttons 'Previous', '1', and 'Next' are at the bottom right of the results panel.

There are two main panels: first, *parameters panel*, users can adjust parameters here; second, *results panel*, many results after users set the parameters will be shown here and users can also download these results.

In the *parameters panel* of “Import Data”, there are two choices for users:

*a. Load experimental data.* When users choose this option, they can upload their own data here. Users should select the right format based on their data and then click “Browse” button to import the data;

*First row as column names:* this means whether the first row is column names. If true, you should choose this parameter.

*First column as row names:* this means whether the first column is row names. If true, you should choose this parameter.

*b. Samples information.* As described in part 1.2, users can choose this option and download the example data to check them locally.

In the *results panel* of “Import Data”, if users don’t upload their data, here will show “StatsPro detects that you did not upload your data. Please upload the expression data, or load the example data to check first” to warn users.

Before uploading expression data, users should also recognize which type their data belongs to and choose the right parameter by adjusting the “Data type”. The instruction of every data type can be found above (*Data Preparation* part).

## Step 1: Upload Original Data

No file selected

☒ First row as column names ?

☐ First column as row names ?

### 3. Data Pre-processing

Users can pre-process their data in this step, including data filtration (i.e. removing those proteins with high proportion of missing values (NAs) and large coefficient of variation (CVs)), normalization (i.e. normalizing protein intensities using median value of each sample), missing value imputation (i.e. all missing values are derived with the k-Nearest Neighbor method<sup>3</sup>).

900

#### 3.1 Parameters

**Step 2: Data Pre-processing** ?

1. Missing value type:  
NA

☐ 2. Count NA by each group or not?

3. NA ratio:  
0.5

☒ 4. Median normalization or not?

☒ 5. Log or not?

6. CV threshold (raw scale):  
0.3

Height for figure:  
900

1. *Missing value type*: what the missing values look like in the expression data, for example, Spectronaut<sup>2,4</sup> software usually export “Filtered” as missing values, so users should change this parameter to “Filtered” if their data contain “Filtered”. *StatsPro* will recognize these characters and replace them with NAs. Any other characters indicating a missing value can be similarly defined.

2. *Count NA by each group or not*: if true, *StatsPro* will count the number of missing values in each

group and calculate the NA ratio. Otherwise, it calculates the NA ratio across all groups, for example, as below:

	A	B	C	D	E	F	G	H	I	J	K	L	M	N	O	P	Q	R	S	T	U	V	W
Peptides	Charges	Uniprot IDs	Phos_Cyc	Phos_Cyc	Phos_Cyc	Phos_Cyc	Phos_Cyc	Phos_Cyc	Phos_Cyc	Phos_Cyc	Phos_Cyc	Phos_Cyc	Phos_Cyc	Phos_Moc	Phos_Moc	Phos_Moc	Phos_Moc	Phos_Moc	Phos_Moc	Phos_Moc	Phos_Moc	Phos_Moc	Phos_Moc
			1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	
NAcetyl (Protein B-ter	2	41KXZ4	79679.09	NA	110380.5	130927.4	82461.98	155724.4	113495.3	138404.3	56171.31	98299.7	NA	NA	151027.6	NA	210179.9	182829.7	151424.3	NA	NA	181321.2	

There are 2 groups (10 biological replicates in each group) here, if users select this parameter, *StatsPro* will calculate 2 NA ratios for this peptide (first group:  $1/10=0.1$ , second group:  $5/10=0.5$ ), otherwise, only one NA ratio:  $6/20=0.3$ .

3. *NA ratio*: the threshold of NA ratio. Those peptides/proteins with NA ratio above this threshold will be removed.

4. *Median normalization or not*: if true, *StatsPro* will process median normalization for original data. (Note, *StatsPro* was not designed to perform sophisticated normalization analysis. Any normalized datasets with NA can be accepted for analysis).

5. *Log or not*: if true, the data will be transformed to the logarithmic scale with base 2.

6. *CV threshold (raw scale)*: the threshold of coefficient of variation. Those peptides/proteins with CV above this threshold will be removed. “raw scale” here means the CV of each peptide/protein is calculate using the data before logarithm transformation.

7. *Height for figure*: users can adjust the height of figures by changing this parameter.

If users set these parameters well, then click “calculate” button, the results will appear on the right panel.

### Step 2: Data Pre-processing

1. Missing value type:

NA

2. Count NA by each group or not?

3. NA ratio:

0.5

4. Median normalization or not?

5. Log or not?

6. CV threshold (raw scale):

0.3

Height for figure:

900

## 4. Methods

Here, 12 published statistical methods for the DEP detection were integrated in *StatsPro* and can be broadly divided into two types: 1. parametric tests, including t test <sup>6</sup>, one-way ANOVA <sup>7</sup>; 2. non-parametric tests, including wilcoxon rank sum test <sup>8</sup>, kruskal-wallis rank sum test <sup>9</sup>, permutation test <sup>10</sup>, limma <sup>11</sup>, SAM <sup>12</sup>, RP <sup>13</sup>, ROTS <sup>14</sup>, MSqRobSum <sup>15</sup>, DEqMS <sup>16</sup>, PLGEM <sup>17</sup>. Therefore, in this step, users can select any of these statistical methods that are currently supported. All methods have been chosen by default. The detailed information about each method can be found in Table S1. In addition, we also provide the reference for every method just below each option on the web:

StatsPro

[Welcome](#)[Import Data](#)[Data Preprocessing](#)[Statistical Methods](#)[Results and Assessments](#)

Step 3: Twelve statistical methods have been integrated here and classified into two categories (Parametric and Non-Parametric). Please select the test methods you want, then click the 'Calculate' button.

Calculate

Method 1: Student's t test (ttest)

Selected Methods

Dear user, you have chosen several methods as below:

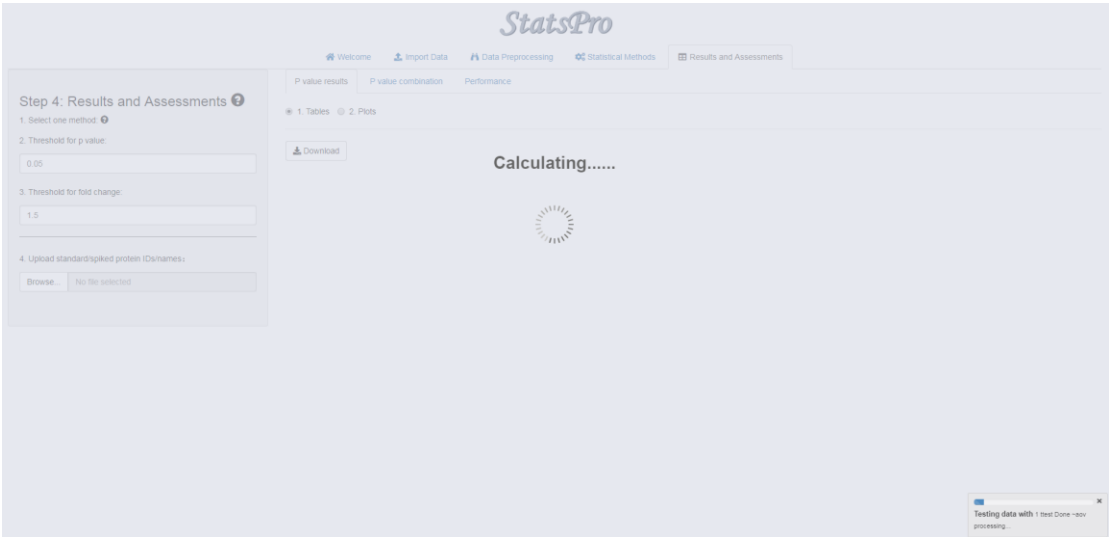

Method 1: ttest  
Method 2: aov  
Method 3: wiltest  
Method 4: kwtest  
Method 5: perm  
Method 6: lmm  
Method 7: sam  
Method 8: rankpro  
Method 9: rts  
Method 10: magrobsum  
Method 11: deqns  
Method 12: pitem

Then click 'OK' and move on...

OK

## 5. Results and Assessments

This step will process statistical testing and performance evaluation of every method that users select in “Methods” step. Click “Results and Assessments”, *StatsPro* will start to calculate, a process bar will appear in the bottom right corner to tell users where it goes:

The result from every statistical method will be shown on the “Results” panel:

Step 4: Results and Assessments

1. Select one method

ttest

2. Threshold for p value:

0.05

3. Threshold for fold change:

1.5

4. Upload standard/spiked protein IDs/names:

## 5.1 Parameters

Step 4: Results and Assessments ?

1. Select one method: ?

ttest

2. Threshold for p value:

0.05

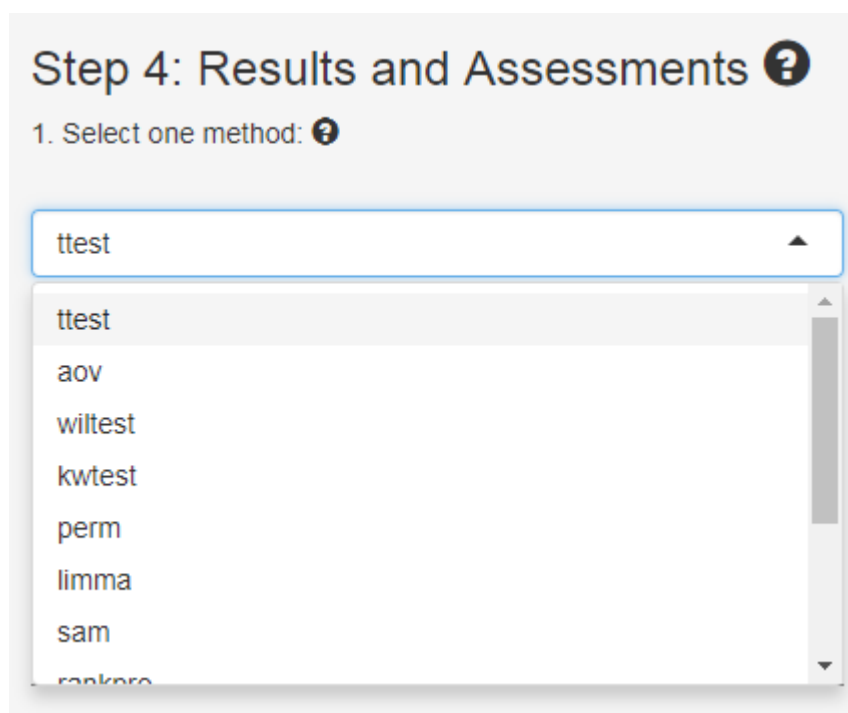

3. Threshold for fold change:

1.5

4. Upload standard/spiked protein IDs/names:

Browse... No file selected

1. *Select one method:* Herein users can change the parameter on the left panel to check relative result, for example, if users select “ttest”, it will show the result derived from ttest method in the “P value results” part:

Step 4: Results and Assessments ?

1. Select one method: ?

ttest

- ttest
- aov
- wiltest
- kwtest
- perm
- limma
- sam
- rankpro

2. *Threshold for p value:* When counting the number of DEPs, those proteins with original P-values or FDR below this threshold will be excluded. The default value is 0.05.

3. *Threshold for fold change:* When counting the number of DEPs, those proteins with fold change above this threshold or below the reciprocal of this fold change will be included. The default value is

1.5. If the proteomics expression intensities are logarithmic, for example, users select the “5. *Log or not?*” parameter in the “Data Pre-processing” part, the threshold for fold change will be  $\log_2(1.5) = 0.585$ , which means that those proteins with absolute fold change above this threshold ( $|\log_2(1.5)| > 0.585$ ) will be included.

4. *Upload standard/spiked protein IDs/names*: If there are spiked proteins (e.g. UPS1) in the samples, users should upload the spiked protein IDs/names here, for example, there are 48 human proteins in the UPS1 and save their UniProt IDs in a .csv file. The example of these IDs is like:

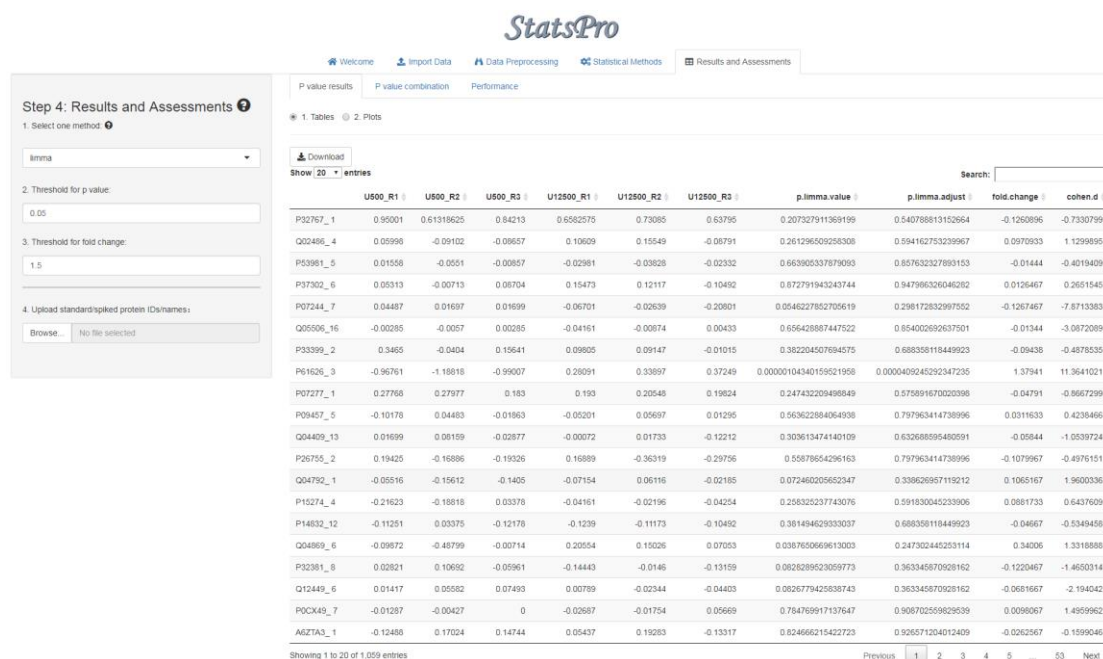

Accession
P61626
P68871
P16083
P00441
P62988
P01344
O76070
P01375
P15559
P63279
Q15843
P61769
P02787
Q06830
P41159
P00167
P69905
P10145
P01127
P08263

## 5.2 Results

The results from 12 statistical methods will be shown in the “P value results” part (please also see the “1. *Select one method*” parameter). In the “1. Tables”, it shows the results including:

- Original P-values* from every statistical method, for example, when selecting the limma method, the “p.limma.value” column contains the original P-values from limma method;
- FDR (also adjusted P-values)*, for example, the “p.limma.adjust” column contains the adjusted P-values from limma method;
- Fold Change*, for example, the values are in the “fold.change” column.
- Cohen's d effect size*, for example the values are in the “cohen.d” column.

Users can click “Download” button to save this result in a .csv file:

In the “2. Plots”, it shows three plots: one, the distributions of original P-values and adjusted P-values; two, the volcano plot, in which the y axis is plotted based on original P-values; three, the volcano plot, in which the y axis is plotted based on adjusted P-values. Users can click “Download” button to save this result in a .pdf file

Next, click “P value combination”. *StatsPro* will calculate the combined P-values based on 6

combination strategies:

**StatsPro**

Welcome Import Data Data Preprocessing Statistical Methods Results and Assessments

P value results P value combination Performance

Step 4: Results and Assessments

1. Select one method

best

2. Threshold for p value:

0.05

3. Threshold for fold change:

1.5

4. Upload standard/protein (Dnames):

Browse ... No file selected

Download

Calculating.....

After calculating, it shows like below. The first six columns contain the P-values obtained from each combination strategy (i.e. p.simes.method, p.fisher.method, p.whitlock.method, p.maxp.method, p.minp.method), and the next six columns contain the adjusted P-values based on the Benjamini-Hochberg (BH) method <sup>18</sup>, which the column names start with “padj”. Users can click “Download” button to save this result in a .csv file:

## 6. How to run this tool locally?

*StatsPro* is an open source software for non-commercial use and all codes can be obtained on our GitHub: <https://github.com/YanglabWCH/StatsPro>. If users want to run *StatsPro* on their own computer, they should operate as below:

As this tool was developed with R, you may:

- a) Install R. You can download R from here: <https://www.r-project.org/>.
- b) Install RStudio. (Recommendatory but not necessary). You can download RStudio from here: <https://www.rstudio.com/>.
- c) Check packages. After installing R and RStudio, you should check whether you have installed these packages (shiny, shinyjs, shinyBS, shinyWidgets, gdata, ggplot2, ggsci, DT, tidyverse, ggExtra, cowplot, readxl, writexl, data.table, Amelia, impute, coin, exactRankTests, limma, samr, RankProd, ROTS, msqrobsum, MSnbase, DEqMS, plgem, effsize, patchwork, survcomp, metaseqR). You may run the codes below to check them:

```
if(!require(pacman)) install.packages("pacman")
pacman::p_load(shiny, shinyjs, shinyBS, shinyWidgets, devtools, gdata, ggplot2, ggsci, DT,
tidyverse, ggExtra, cowplot, readxl, writexl, data.table, Amelia, impute, coin, exactRankTests,
limma, samr, RankProd, ROTS, msqrobsum, MSnbase, DEqMS, plgem, effsize, patchwork,
survcomp, metaseqR)
```

Please note, if you find some packages cannot be installed directly using the above command, you can find them in the GitHub source and install them by, for example:

```
library(devtools)
install_github("statOmics/MSqRobSum")
```

- d) Run this tool locally

```
if(!require(StatsPro)) devtools::install_github("YanglabWCH/StatsPro")
library(StatsPro)
StatsPro_app()
```

Then *StatsPro* will be started as below (same as the online version), and the detailed operation about *StatsPro* can be found in the Supplementary Notes part 1-5 above:

# StatsPro

[Welcome](#)[Import Data](#)[Data Preprocessing](#)[Statistical Methods](#)[Results and Assessments](#)

## Welcome to StatsPro

**StatsPro** integrates 12 common statistical methods and 6 P-value combination strategies, and then provides three evaluation criteria to assess the performance of each method or strategy. This tool is expected to help scientists detect the differentially expressed proteins and realize the ability of different statistical methods in a systematic view.

StatsPro is developed by [R shiny \(Version 1.3.2\)](#), and is free and open to all users with no login requirement. It can be readily accessed by all popular web browsers including Google Chrome, Mozilla Firefox, Safari and Internet Explorer 10 (or later), and so on. We would highly appreciate that if you could send your feedback about any bug or feature request to Shisheng Wang at [wsslearning@omicsolution.com](mailto:wsslearning@omicsolution.com).

~~ Enjoy yourself in StatsPro ~~

## II. Supplementary tables and figures

**Table S1.** Description of 18 different approaches (12 statistical methods and 6 P-value combination strategies).

Class	Abbreviation	Algorithm Description	Remarks & Suggestions	Function	Package/Reference
1. Parametric tests	ttest	Student's t-test. It is usually used to determine if the means of two data sets are significantly different from each other.	1. They assume that the data should follow a normal distribution when using these methods, but please note StatsPro do not process normality test.  2. By default, when dealing with two groups of samples, aov is same as ttest with treating the two variances as being equal.	t.test	stats <sup>6</sup>
	aov	Analysis of variance (ANOVA). It provides a statistical test of whether two or more population means are equal.		aov	stats <sup>7</sup>
2. Non-parametric tests	wiltest	Wilcoxon rank sum test. It is used to compare two groups of samples to assess whether their population mean ranks differ.	Non-parametric tests are methods of statistical analysis that do not require a distribution to meet the required assumptions to be analyzed (especially if the data is not normally distributed).	wilcox.test	stats <sup>8</sup>
	kwtest	Kruskal-Wallis rank sum test. It is an extension of the Wilcoxon rank sum test to allow the comparison of two or more than two independent groups.		kruskal.test	stats <sup>9</sup>
	perm	Permutation test. It permutes the		perm.test	exactRankTests <sup>10</sup>

		observed data by assigning different outcome values randomly to each observation from among the set of actually observed outcomes without replacement.			
	limma	Linear models for microarray data. It fits a linear model to determine differential expression. While most of the functionality of limma has been developed for microarray data, the model fitting routines of limma are useful for many other types of data, for example proteomics data.		lmFit, eBayes	limma <sup>11</sup>
	sam	Significance analysis of microarrays. It is a statistical technique initially for finding significant genes in a set of microarray experiments and assigns a score to each gene on the basis of change in gene expression relative to the standard deviation of repeated measurements.		samr	samr <sup>12</sup>
	rankpro	Rank product. It ranks the proteins according to their fold changes.		RankProducts	RankProd <sup>13</sup>

	rots	Reproducibility optimized test statistic. It aims to rank genomic features of interest (such as genes, proteins and transcripts) in order of evidence for differential expression in two-group comparisons.		ROTS	ROTS <sup>14</sup>
	msqrobsum	Robust differential protein expression analysis for label-free quantitative proteomics and robust peptide expression summarization. It provides robust protein level summaries that account for peptide specific effects, which are then further processed using robust ridge regression.		msqrobsum	msqrobsum <sup>15</sup>
	deqms	Differential Expression analysis of quantitative Mass Spectrometry data. It is a robust statistical method developed on top of limma and implemented specifically for differential protein expression analysis in mass spectrometry data.		contrasts.fit, eBayes, spectraCounte Bayes	DEqMS <sup>16</sup>
	plgem	Power law global error model. It uses highly replicated microarray data to empirically determine the true variance		plgem.fit, plgem.obsStn, plgem.resampl	plgem <sup>17</sup>

		versus mean dependence that exists in this type of data.		edStn, plgem.pValue	
3. P-value combination strategies	simes	Let $p_{i1}, p_{i2}, \dots, p_{im}$ be the P-value scores returned for gene i after the application of m statistical tests. Let also $p_{i(1)}, p_{i(2)}, \dots, p_{i(m)}$ be the aforementioned P-values sorted in increasing order. Then, according to Simes' method, the combined P-value can be: $p_i^* = \min\{p_{i(k)}/k\}, k \in (1, \dots, m)$	P-value combination means combining different P-values from various statistical methods based on one certain rule. In the left cells, i means ith gene (for this work, it means ith protein), j means jth statistical method, m means the total number of statistical methods (i.e. m=12 if users select all statistical methods).	combine.simes	metaseqR <sup>19</sup>
	fisher	According to the Fisher's method, let f be the statistic defied by the natural logarithm of the product of m individual P-values (from m statistical tests) multiplied by -2: $f = -2 \sum_{j=1}^m \ln p_{ij}$ . f follows an $X^2$ distribution with 2m degrees of freedom, which can be used to derive the combined P-value from m statistical tests.		fisher.method	
	whitlock	According to Whitlock's weighted Z-method, the weighted Z statistic for each gene i: $Z_j^w = \sum_{j=1}^m w_j Z_j /$		combine.test	

		$\sqrt{\sum_{j=1}^m w_j^2}$ . It follows the standard Normal distribution $N(0,1)$ , which can be used to derive the P-value of the combined tests.			
	maxp	The combined P-value is: $p_i^* = \max\{p_{ij}\}, j \in (1, \dots, m)$		combine.maxp	
	minp	The combined P-value is: $p_i^* = \min\{p_{ij}\}, j \in (1, \dots, m)$		combine.minp	
	pandora	The combined P-value is: $p_i^* = \prod_{j=1}^m p_{ij}^{w_j}$ , with $\sum_{j=1}^m w_j = 1$ , where $w_j$ represent automatically assigned or user-specific weights for the $j$ statistical tests performed.		combine.weight t	
Cohen's d effect size	Cohend	For two independent groups, effect size can be measured by the standardized difference between two means: $\text{Cohend} = (M_1 - M_2)/s$ , where $M_1 - M_2$ is the difference between the group means, $s$ is the standard deviation of either group.	Cohen classified effect sizes as small ( $d = 0.2$ ), medium ( $d = 0.5$ ), and large ( $d \geq 0.8$ ).	cohen.d	effsize <sup>20</sup>
